

Polygon Clipping I

1. Always start the clipping process with the *vertex that goes from outside to inside and has the largest (or, smallest) y-coordinate* if the clipping edge is vertical (see the next slide for such a vertex). Otherwise start with the vertex that goes from outside to inside and has the largest (or, smallest) x-coordinate. (*Totally, four cases*)

2. Each time you move from an “In” vertex to an “out” vertex, compute the intersection point, append the intersection point to the current vertex list and then output the current vertex list. So for the following polygon, you would get the following output vertex lists.

Start clipping process with this vertex

- $P1: u_0 \rightarrow v_1 \rightarrow u_1$
- $P2: u_2 \rightarrow v_3 \rightarrow u_3$
- $P3: u_4 \rightarrow v_5 \rightarrow u_5$
- $P4: u_6 \rightarrow v_7 \rightarrow u_7$
- $P5: u_8 \rightarrow v_9 \rightarrow u_9$
- $P6: u_{10} \rightarrow v_{11} \rightarrow u_{11}$

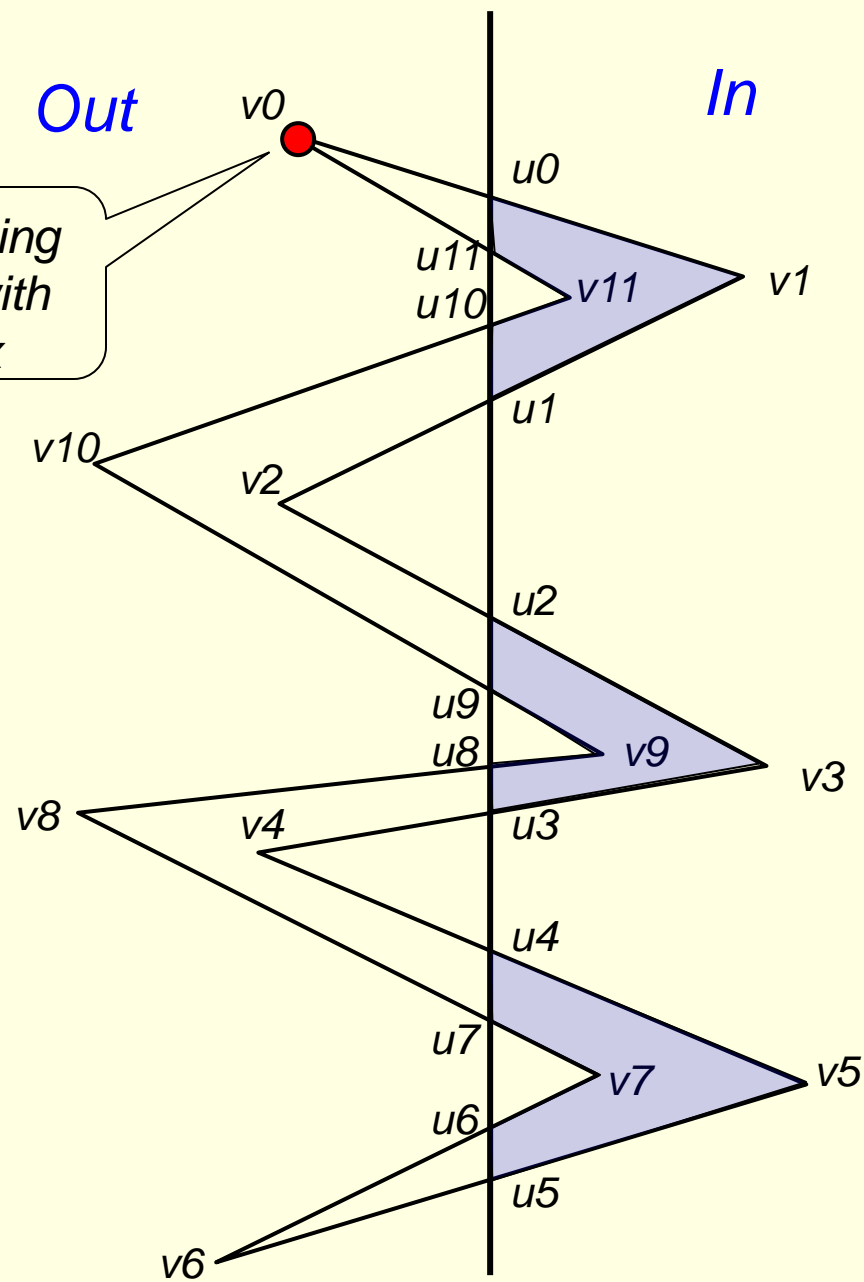

Polygon Clipping I

3. For each output vertex list, check if the start vertex and end vertex of any other vertex list are between the start vertex and end vertex of this list vertically (if the clipping edge is vertical) or horizontally (if the clipping edge is horizontal). If there is such a vertex list for this output vertex list, then these two vertex lists should be merged into a single list.

For instance, for the above polygon, vertex lists P1 and P6 should be merged into a single list. The merging process is simple, simply append P6 to P1.

After this step, we would have only 3 vertex lists for the given polygon. These sub-polygons are then clipped against other bounding edges of the window.

Start clipping process with this vertex

$P1: u_0 \rightarrow v_1 \rightarrow u_1$

$P2: u_2 \rightarrow v_3 \rightarrow u_3$

$P3: u_4 \rightarrow v_5 \rightarrow u_5$

$P4: u_6 \rightarrow v_7 \rightarrow u_7$

$P5: u_8 \rightarrow v_9 \rightarrow u_9$

$P6: u_{10} \rightarrow v_{11} \rightarrow u_{11}$

$P1: u_0 \rightarrow v_1 \rightarrow u_1 \rightarrow u_{10} \rightarrow v_{11} \rightarrow u_{11}$

$P2: u_2 \rightarrow v_3 \rightarrow u_3 \rightarrow u_8 \rightarrow v_9 \rightarrow u_9$

$P3: u_4 \rightarrow v_5 \rightarrow u_5 \rightarrow u_6 \rightarrow v_7 \rightarrow u_7$

Polygon Clipping I

4. If a vertex list does not contain any other vertex list as a subset, such as the ones shown in the next slide, the vertex list forms closed sub-polygon by itself.

Start clipping process with this vertex

- $P1: u_0 \rightarrow v_1 \rightarrow u_1$
- $P2: u_2 \rightarrow v_3 \rightarrow u_3$
- $P3: u_4 \rightarrow v_5 \rightarrow u_5$
